

the master mode clock division factor is cleared when the MICROWIRE/PLUS BUSY flag is low. The clock division factor is relative to the instruction cycle frequency. For example, if the COP800 is operating with an internal clock of 1 MHz, the SK clock rate would be 500 kHz, 250 kHz, or 125 kHz for SL1 and SL0 values of 00, 01 and 10 (or 11) respectively.

**TABLE II**

CNTRL Register (Address X'00EE)

The Timer1 (T1) and MICROWIRE control register contains the following bits:

- SL1 & SL0 Select the MICROWIRE clock divide by (00 = 2, 01 = 4, 1X = 8)
- IEDG External Interrupt Edge Polarity Select (0 = Rising Edge, 1 = Falling Edge)
- MSEL Selects G5 and G4 as MICROWIRE Signals SK and SO Respectively
- T1C0 Timer T1 Start/Stop Control in Timer Modes 1 and 2  
Timer T1 Underflow Interrupt Pending Flag in Timer Mode 3
- T1C1 Timer T1 Mode Control Bit
- T1C2 Timer T1 Mode Control Bit
- T1C3 Timer T1 Mode Control Bit

T1C3	T1C2	T1C1	T1C0	MSEL	IEDG	SL1	SL0
------	------	------	------	------	------	-----	-----

Bit 7 Bit 0

SL1	SL0	SK
0	0	$2 \times t_c$
0	1	$4 \times t_c$
1	x	$8 \times t_c$

Where  $t_c$  is the instruction cycle clock

**MICROWIRE/PLUS MASTER MODE OPERATION**

In the MICROWIRE/PLUS master mode, the BUSY flag of PSW (Processor Status Word) is used to control the shifting

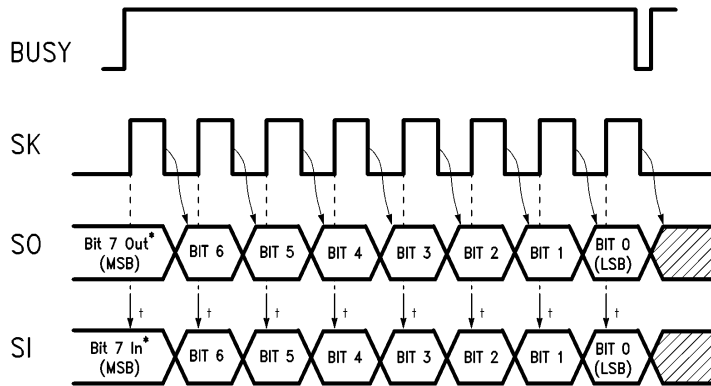

of the MICROWIRE/PLUS 8-bit shift register. Setting the BUSY flag causes the SIOR register to shift out 8 bits of data from SO at the high order end of the shift register. During the same time, 8 new bits of data from SI are shifted into the low order end of the SIOR register. The BUSY flag is automatically reset after the 8 bits of data have been shifted (Figure 2). The COP888XX series of microcontrollers provide a vectored maskable interrupt when the BUSY goes low indicating the end of an 8-bit shift. Input data is clocked into the SIOR register from the SI pin with the rising edge of the SK clock, while the MSB of the SIOR is shifted onto the SO pin with the falling edge of the SK clock. The user may reset the BUSY bit by software to allow less than 8 bits to shift. However, the user should ensure that the software BUSY resets only occurs when the SK clock is low, in order to avoid a narrow SK terminal clock.

**MICROWIRE/PLUS SLAVE MODE OPERATION**

In the MICROWIRE/PLUS Slave mode of operation the SK clock is generated by an external source. Setting the MSEL bit in the CNTRL register enables the SO and SK functions onto the G Port. The SK pin must be configured as an input and the SO pin configured as an output by resetting and setting the appropriate bits in the Port G configuration register. The user must set the BUSY flag immediately upon entering the Slave mode. After eight clock pulses the Busy flag will be cleared and the sequence may be repeated. However, in the Slave mode the COP888 series does not shift data if the BUSY flag is reset, whereas the COP820C and COP840C continues to shift regardless of the BUSY flag, if the SK clock is active.

**MICROWIRE/PLUS ALTERNATE SK MODE**

The COP888XX series of microcontrollers also allow an additional Alternate SK Phase Operation. In the normal mode data is shifted in on the rising edge of the SK clock and data is shifted out on the falling edge of the SK clock (Figure 2). The SIOR register is shifted on each falling edge of the SK clock. In the alternate SK phase operation, data is shifted in on the falling edge of the SK clock and data is shifted out on the rising edge of the SK clock (Figure 3).

TL/DD/10252-2

\*This bit becomes valid immediately after loading the SIOR register of the transmitting device.

†Arrows indicate points at which SI is sampled.

**FIGURE 2. MICROWIRE/PLUS Timing**

TL/DD/10252-3

↑ Arrows indicates points at which SI is sampled.

**FIGURE 3. Alternate Phase SK Clock Timing**

A control flag, SKSEL, allows either the normal SK clock or alternate SK clock to be selected. Resetting SKSEL selects the normal SK clock and setting SKSEL selects the alternate SK clock for the MICROWIRE/PLUS logic. The SKSEL flag is mapped into the G6 configuration bit. The SKSEL flag is reset after power up, selecting the normal SK clock signal. The alternate mode facilitates the usage of the MICROWIRE/PLUS protocol for serial data transfer between peripheral devices which are not compatible with the normal SK clock operation, i.e., shifting in data on the rising edge of the SK clock and shifting in data on the rising edge of the SK clock.

#### MICROWIRE/PLUS SAMPLE PROTOCOL

This section gives a sample MICROWIRE/PLUS protocol using a COP888CL and COP840C. The slave mode operating procedure for this sample protocol is explained, and a timing illustration of the protocol is provided.

1. The MSEL bit in the CNTRL register is set to enable MICROWIRE; G0 ( $\overline{CS}$ ) and G5 (SK) are configured as inputs and G4 (SO) as an output. G6 (SI) is always an input.
2. Chip Select line ( $\overline{CS}$ ) from master device is connected to G0 of the slave device. An active-low level on  $\overline{CS}$  line causes the slave to interrupt.
3. From the high-to-low transition on the  $\overline{CS}$  line, there is no data transfer on the MICROWIRE until time "T" (See Figure 4).
4. The master initiates data transfer on the MICROWIRE by turning on the SK clock.
5. A series of data transfers take place between the master and slave devices.
6. The master pulls the  $\overline{CS}$  line high to end the MICROWIRE operation. The slave device returns to normal mode of operation.

#### SLAVE MODE OPERATING PROCEDURE

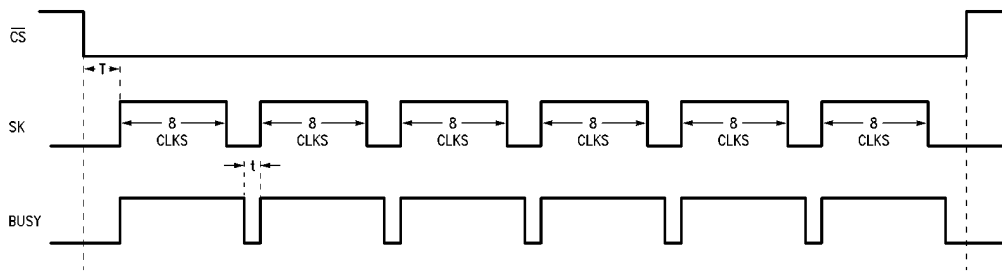

1. The MSEL bit in the CNTRL register is set to enable MICROWIRE; G0 ( $\overline{CS}$ ) and G5 (SK) are configured as inputs and G4 (SO) as an output. G6 (SI) is always an input.
2. Normal mode of operation until interrupted by  $\overline{CS}$  going low.

3. Set the BUSY flag and load SIOR register with the data to be sent out on SO. (The shift register shifts 8 bits of data from SO at the high order end of the shift register. During the same time, 8 new bits of data from SI are loaded into the low order end of the shift register.)
4. Wait for the BUSY flag to reset. (The BUSY flag is automatically reset after 8 bits of data have been shifted).
5. If data is being read in, the user should save contents of the SIOR register.
6. The prearranged set of data transfers are performed.
7. Repeat steps 3 through 6. The user must ensure steps 3 through 6 are performed in time "t" (See Figure 4) as agreed upon in the protocol.

#### DIFFERENCES BETWEEN COP888 AND COP820/COP840

The COP888 series MICROWIRE/PLUS feature differs from that of the COP820/COP840 in some respects. The COP888 series can be configured to interrupt the processor after the completion of a MICROWIRE/PLUS operation indicated by the BUSY flag going low. The COP888 series supports a vectored interrupt scheme. Two bytes of program memory space are reserved for each interrupt source. The user would do any required context switching and then program a VIS (Vector Interrupt Select) instruction in order to branch to the interrupt service routine of the highest priority interrupt enabled and pending at the time of the VIS instruction. The addresses of the different interrupt service routines are chosen by the user and stored in ROM in a table starting at 0yE0 where "y" depends on the 256 byte block (0y00 to 0yFF) in which the VIS instruction is located. The vector address for the MICROWIRE/PLUS interrupt is 0yF2-0yF3.

Secondly, the COP888 series supports the alternate SK phase mode of MICROWIRE/PLUS operation. This feature facilitates the usage of the MICROWIRE/PLUS protocol for serial data transfer between peripheral devices which are not compatible with the normal SK clock operation, i.e., shifting data out on the falling edge of SK clock and shifting in data on the rising edge of the SK clock.

TL/DD/10252-4

FIGURE 4. MICROWIRE/PLUS Sample Protocol Timing Diagram

**INTERFACE CONSIDERATIONS**

To preserve the integrity of data exchange using MICROWIRE/PLUS, two aspects have to be considered:

1. Serial data exchange timing.
2. Fan-out/fan-in requirements.

Theoretically, infinite devices can access the same interface and be uniquely enabled sequentially in time. In practice, however, the actual number of devices that can access the same serial interface depends on the following: System data transfer rate, system supply requirement, capacitive loading on SK and SO outputs, the fan-in requirements of the logic families or discrete devices to be interfaced.

**HARDWARE INTERFACE**

For proper data transfer to occur the output should be able to switch between a HIGH level and a LOW level in a predetermined amount of time. The transfer is strictly synchronous and the timing is related to the MICROWIRE/PLUS system clock (SK). For example, if a COPS controller outputs a value at the falling edge of the clock and is latched in by the peripheral device at the rising edge, then the following relationship has to be satisfied:

$$t_{\text{DELAY}} + t_{\text{SETUP}} \leq t_{\text{CK}}$$

where  $t_{\text{CK}}$  is the time from data output starts to switch to data being latched into the peripheral chip,  $t_{\text{SETUP}}$  is the setup time for the peripheral device where the data has to be at a valid level, and  $t_{\text{DELAY}}$  is the time for the output to read the valid level.  $t_{\text{CK}}$  is related to the system clock provided by the SK pin of the COPS controller and can be increased by increasing the COPS instruction cycle time.

Besides the timing requirements, system supply and fan-out/fan-in requirements also have to be considered when interfacing with MICROWIRE/PLUS. To drive multi-devices on the same MICROWIRE/PLUS, the output drivers of the controller need to source and sink the total maximum leakage current of all the inputs connected to it and keep the signal level within the valid logic "1" and "0" input voltage levels. Thus, if devices of different types are connected to the same serial interface, output driver of the controller must satisfy all the input requirements of each device. Similarly, devices with TRI-STATE® outputs, when connected to the SI input, must satisfy the minimum valid input level of the controller and the maximum TRI-STATE® leakage current of all outputs.

So, for devices that have incompatible input levels or source/sink requirements, external pull-up resistors or buffers are necessary to provide level-shifting or driving.

### TYPICAL APPLICATIONS

A whole family of off-the shelf devices exist that are directly compatible with MICROWIRE/PLUS protocol. This allows direct interface with the COP800 family of microcontrollers. Table III provides a summary of the existing devices, their function and specification.

### NMC9306-COP888CG INTERFACE

The pin connection involved in interfacing an NMC9306 (COP494), a 256 bit E<sup>2</sup>PROM, with the COP888CG microcontroller is shown in Figure 5. Some notes on the NMC9306 interface requirements are:

1. The SK clock frequency should be in the 0 kHz–250 kHz range.
2.  $\overline{CS}$  low period following an Erase/Write instruction must not exceed 30 ms maximum. It should be set at typical or minimum specification of 10 ms.

3. The start bit on DI must be set by a “0” to “1” transition following a  $\overline{CS}$  enable (“0” to “1”) when executing any instruction. One  $\overline{CS}$  enable transition can only execute one instruction.
4. In the read mode, following an instruction and data train, the DI can be a “don’t care”, while the data is being outputted, i.e., for the next 17 bits or clocks. The same is true for other instructions after the instruction and data has been fed in.
5. The data out train starts with a dummy bit 0 and is terminated by chip deselect. Any extra SK cycle after 16 bits is not essential.  
If  $\overline{CS}$  is held on after all 16 of the data bits have been outputted, the DO will output the state of DI until another  $\overline{CS}$  LO to HI transition starts a new instruction cycle.
6. After a read cycle, the  $\overline{CS}$  must be brought low for one SK clock cycle before another instruction cycle starts.

### Instruction Set

Commands	Start Bit	Opcode	Address	Comments
READ	1	0000	A3A2A1A0	Read Register 0–15
WRITE	1	1000	A3A2A1A0	Write Register 0–15
ERASE	1	0100	A3A2A1A0	Erase Register 0–15
EWEN	1	1100	00 01	Write/Erase Enable
ENDS	1	1100	00 10	Write/Erase Disable
***WRAL	1	1100	01 00	Write All Registers
ERAL	1	1100	01 01	Read All Registers

Where A3A2A1A0 corresponds to one of the sixteen 16-bit registers.

All commands, data in, and data out are shifted in/out on the rising edge of the SK clock.

Write/Erase is then done by pulsing  $\overline{CS}$  low for 10 ms.

All instructions are initiated by a LO–HI transition on  $\overline{CS}$  followed by a LO–HI transition on DI.

READ— After read command is shifted in DI becomes don’t care and data can be read out on data out, starting with dummy bit zero.

WRITE— Write command shifted in followed by data in (16 bits) the  $\overline{CS}$  pulsed low for 10 ms minimum.

ERASE/ERASE ALL— Command shifted in followed by  $\overline{CS}$  low.

WRITE ALL— Pulsing  $\overline{CS}$  low for 10 ms.

ENABLE/DISABLE— Command shifted in.

A detailed explanation of the E<sup>2</sup>PROM timing diagrams, instruction set and the various considerations could be found in the NMC9306 data sheet. A source listing of the software to interface the NMC9306 with the COP888CG is provided.

### COP472-COP820 Interface

The pin connection required for interfacing COP472-3 Liquid Crystal Display (LCD) Controller with COP820C microcontroller is shown in *Figure 6*. The COP472-3 drives a multiplexed liquid crystal display directly. Data is loaded serially and is held in internal latches. One COP472-3 can drive 36 segments and two or more COP472-3's can be cascaded to drive additional segments as long as the output loading capacitance does not exceed specifications.

The COP472-3 requires 40 information bits: 36 data and 4 control. The function of each control bit is described briefly. Data is loaded in serially, in sets of eight bits. Each set of segment data is in the following format:

SA	SB	SC	SD	SE	SF	SG	SH
----	----	----	----	----	----	----	----

Data is shifted into an eight bit shift register. The first bit of data is for segment H, digit 1, and the eighth bit is for segment A, digit 1. A set of eight bits are shifted in and then

loaded into the digit one latches. The second, third, and fourth set is then loaded sequentially. The fifth set of data bits contain special segment data and control data in the following format:

SYNC	Q7	Q6	X	SP4	SP3	SP2	SP1
------	----	----	---	-----	-----	-----	-----

The first four bits shifted in contain the special character segment data. The fifth bit is not used. The sixth and seventh bits program the COP472-3 as a stand alone LCD driver or as a master or slave for cascading COP472-3's. The Table IV summarizes the function of bits six and seven.

The eighth bit is used to synchronize two COP472-3's to drive an 8½ digit display. A detailed explanation of the various timing diagrams, loading sequence and segment/backplane multiplex scheme can be found in the data sheets of COP472-3. The source listing of the software used in the interface is provided.

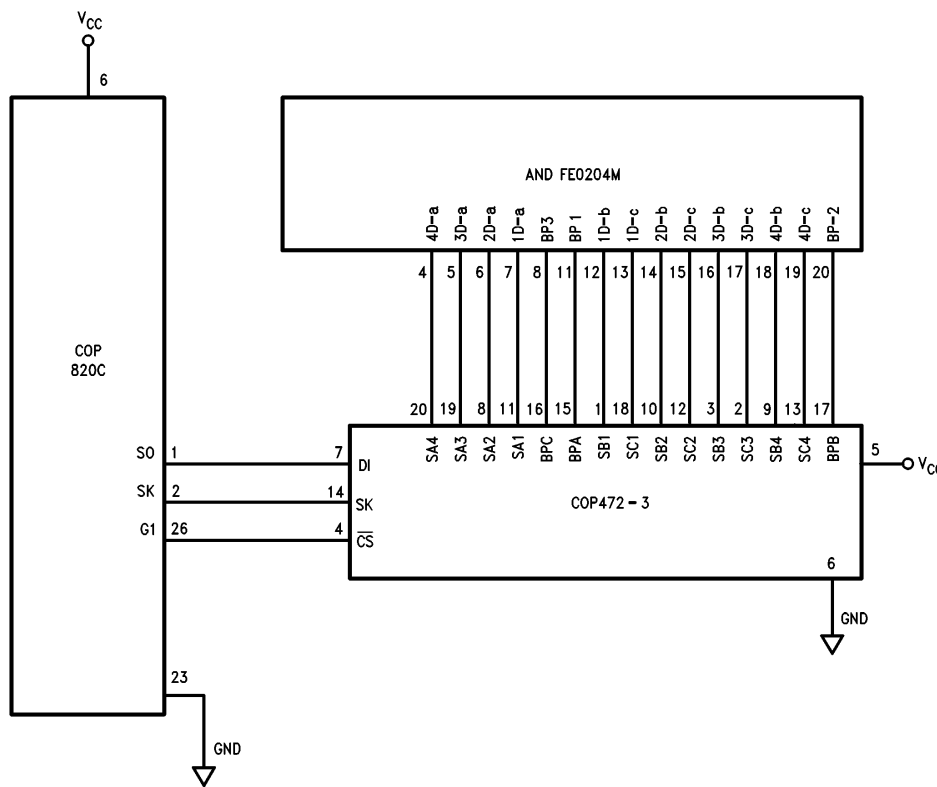

FIGURE 6. COP472-COP820C Interface

## SOURCE LISTING

;THIS PROGRAM DISPLAYS FOUR DIGITS OF THE RAM SPECIFIED BY; THE ADDRESS POINTER "HEAD" ON A 4 DIGIT 3  
;DECIMAL POINT (MULTIPLEXED) LCD DISPLAY. THE DATA STREAM IS SENT OUT SERIALY THROUGH THE  
;MICROWIRE/PLUS INTERFACE TO THE COP472 LCD DISPLAY DRIVER. NOTE: THE RAM CONTENTS SHOULD BE  
;BETWEEN "0" AND "F".

The code listed in this App Note is available on Dial-A-Helper.

Dial-A-Helper is a service provided by the Microcontroller Applications Group. The Dial-A-Helper system provides access to an automated information storage and retrieval system that may be accessed over standard dial-up telephone lines 24 hours a day. The system capabilities include a MESSAGE SECTION (electronic mail) for communicating to and from the Microcontroller Applications Group and a FILE SECTION mode that can be used to search out and retrieve application data about NSC Microcontrollers. The minimum system requirement is a dumb terminal, 300 or 1200 baud modem, and a telephone.

With a communications package and a PC, the code detailed in this App Note can be downloaded from the FILE SECTION to disk for later use. The Dial-A-Helper telephone lines are:

Modem (408) 739-1162  
Voice (408) 721-5582

#### LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
