DATA TERMINAL
TECHNICAL INFORMATION

HEWLETT  PACKARD

1.0 INTRODUCTION.

This section contains design and application information for the Backplane Module and establishes the rules for interfacing between the various functional modules and the backplane (terminal data bus). The backplane is a printed-circuit board mounted to the bottom of the terminal base and contains a power supply connector and a number of printed circuit edge connectors. In addition to providing power to the functional modules, it supplies the 4.915 MHz System Clock (SYS CLK) and System Power On (PWR ON) signals. Data, address, and control signals for communication between the various functional modules is also supplied by the Backplane Module. The bus is the primary data path between the processor and memory, display and memory, and the processor and peripherals (such as the keyboard, data comm, display, printer, and the CTU). All communication on the bus occurs in a serially shared mode, with each byte transfer being an independent non-interruptable transaction.

2.0 OPERATING PARAMETERS.

A summary of operating parameters for the Backplane Module is contained in tables 1.0 through 3.2.

Table 1.0 Physical Parameters

Part Number	Nomenclature	Size (L x W x D) +/-0.100 Inches	Weight (Pounds)
02640-60153	Backplane PCA (9 Slot)	6.3 x 5.3 x 0.8	0.56
02640-60002	Backplane Extender PCA (6 Slot)	5.3 x 3.7 x 0.6	0.38
02640-60052	Mainframe Assembly	N/A	N/A
02640-60075	Backplane PCA (15 Slot)	9.8 x 5.3 x 0.8	0.81

1.0 INTRODUCTION.

This section contains design and application information for the Backplane Module and establishes the rules for interfacing between the various functional modules and the backplane (terminal data bus). The backplane is a printed-circuit board mounted to the bottom of the terminal base and contains a power supply connector and a number of printed circuit edge connectors. In addition to providing power to the functional modules, it supplies the 4.915 MHz System Clock (SYS CLK) and System Power On (PWR ON) signals. Data, address, and control signals for communication between the various functional modules is also supplied by the Backplane Module. The bus is the primary data path between the processor and memory, display and memory, and the processor and peripherals (such as the keyboard, data comm, display, printer, and the CTU). All communication on the bus occurs in a serially shared mode, with each byte transfer being an independent non-interruptable transaction.

2.0 OPERATING PARAMETERS.

A summary of operating parameters for the Backplane Module is contained in tables 1.0 through 3.2.

Table 1.0 Physical Parameters

Part Number	Nomenclature	Size (L x W x D) +/-0.100 Inches	Weight (Pounds)
02640-60153	Backplane PCA (9 Slot)	6.3 x 5.3 x 0.8	0.56
02640-60002	Backplane Extender PCA (6 Slot)	5.3 x 3.7 x 0.6	0.38
02640-60052	Mainframe Assembly	N/A	N/A

3.0 FUNCTIONAL DESCRIPTION - SIGNALS. Refer to the schematic diagrams (figures 1, 2, and 3), typical memory module interface (figure 4), typical I/O module interface (figure 5), bus controller circuit (figure 6), bus controller states (figure 7), bus controller timing diagram (figure 8), and parts lists, (02640-60153, 02640-60002, 02640-60052, 02640-60075, 02640-60138, 02644-60001, 02644-60003, and 02645-60005) located in the appendix.

3.1 ADDR0 through ADDR15. These signals are defined as module address lines 0 through 15 and are used to define which module is being addressed, and which function (for an I/O module) or which byte (for a memory module) within the addressed module is being addressed. Bit assignments are as follows with ADDR0 being the least significant bit.

MEMORY ADDRESS SIGNALS	<u>A15</u>	<u>A14</u>	<u>A13</u>	<u>A12</u>	<u>A11</u>	<u>A10</u>	<u>A9</u>	<u>A8</u>	<u>A7</u>	<u>A6</u>	<u>A5</u>	<u>A4</u>	<u>A3</u>	<u>A2</u>	<u>A1</u>	<u>A0</u>
------------------------	------------	------------	------------	------------	------------	------------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------

I/O MODULE ADDRESS SIGNALS	-	-	-	-	<u>M2</u>	<u>M1</u>	<u>M0</u>	<u>X4</u>	<u>X7</u>	<u>X6</u>	<u>X5</u>	<u>M3</u>	<u>X3</u>	<u>X2</u>	<u>X1</u>	<u>X0</u>
----------------------------	---	---	---	---	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------	-----------

M's = I/O Module Select Code Bits
X's = I/O Module Subfunction Strobe Bits
A's = Memory Module Address Bits

3.2 BUS0 through BUS7. These signals are defined as data bus bits 0 through 7. BUS0 is the least significant bit. All eight bits are transferred without modification over the bus. There is no parity check or other verification.

3.3 SYS CLK. This signal is the 4.915 MHz System Clock used to synchronize bus operations. All bus control signals must be changed only on negative transitions of this clock. This is a 50 per cent duty cycle TTL signal.

3.4 I/O. This is the input output/memory signal and when low, indicates that address lines are to be interpreted as I/O module addresses and strobes. When high, it indicates that addresses are to be interpreted as memory references.

- 3.5 WRITE. When low, this signal indicates that the current bus cycle is a write or output operation (data going out of the processor, to the modules). When high, it indicates that a read or input operation is in progress (data going into the processor from the modules).
- 3.6 PWR ON. System Power On will be low for the first 50 milliseconds after power is turned on; then it goes high and remains high as long as power is on. The PWR ON line should be used to initialize any circuits whose beginning states are important. It can be pulled manually low with power still on by pressing the RESET TERMINAL key on the keyboard. (RESET TERMINAL is a switch contact which pulls the line low for as long as the switch is depressed.) (Refer to module section 13255-91018 for the exact function of RESET TERMINAL key.)
- 3.7 RUN. This signal can be used to halt the processor. When pulled low, it prevents the processor from accessing the bus again, thus keeping the processor in a waiting state. When the RUN line is released, the processor will resume running again. This line is not normally used, and is provided primarily for use with diagnostic and debugging aids to implement run/halt and processor single-cycle operations.
- 3.8 PROC ACTIVE. Processor Active indicates that the bus cycle currently in progress is being controlled by the processor. This line is not normally used, and is provided primarily for debugging and diagnostic purposes to implement processor single-cycle and processor instruction flow monitoring; and so that a sampler module can monitor bus operations and be able to distinguish processor transactions from display memory access (DMA) or other transactions.
- 3.9 PRIOR IN. When high, the Priority In line indicates to a bus controller that no higher priority device is contending for control of the bus. When PRIOR IN is low, it indicates that a higher priority controller is attempting to get the bus.
- 3.10 PRIOR OUT. The Priority Out line is used by a controller to signal other lower priority controllers that they must wait before attempting to take control of the bus. A low level indicates that the bus is not available. This signal is directly connected to PRIOR IN of the next lower priority module in a daisy-chain from module to module.
- 3.11 BUSY. When low, BUSY indicates to all other controllers that the bus is currently being controlled and is not available. This is the method by which a low priority controller maintains control while a high pri-

riority controller is attempting to gain control. The priority chain is used to resolve which of the multiple controllers simultaneously contending for control will gain the control when the bus becomes not busy (bus is available).

3.12 $\overline{\text{REQ}}$. Request is the signal which indicates to the addressed module that the data on the bus is valid. Data being output by the processor is valid before $\overline{\text{REQ}}$ goes low, while it is low, and after it goes high. Therefore, $\overline{\text{REQ}}$ may be used to clock a flip-flop on either rising or falling edges, or to enable a latch. If data is being read into the processor, $\overline{\text{REQ}}$ is used to signal an addressed module to drive data onto the bus. When $\overline{\text{REQ}}$ again goes high, data should immediately be removed from the bus. The processor will provide address and data setup and hold time for data being sent to a module, but will sample the data lines only at the trailing (rising) edge of $\overline{\text{REQ}}$ when reading data from a module.

3.13 $\overline{\text{WAIT}}$. $\overline{\text{WAIT}}$ may be pulled low by an addressed module to signal a controller that the module will be unable to respond to a 400 nanosecond $\overline{\text{REQ}}$. $\overline{\text{WAIT}}$ causes the controller to hold $\overline{\text{REQ}}$ low in increments of 200 nanoseconds until the addressed module releases $\overline{\text{WAIT}}$, then $\overline{\text{REQ}}$ will go high at the next SYS CLK falling edge. An addressed module should release $\overline{\text{WAIT}}$ as soon as valid data is put on the bus, but just after a falling SYS CLK edge, so that the data will have at least 200 nanoseconds to settle before being sampled (at the end of $\overline{\text{REQ}}$).

3.14 $\overline{\text{ATN}}$. Attention (interrupt request), is used by a module to request service from the processor. After the processor has read the status of the interrupting module, the module should release the $\overline{\text{ATN}}$ line.

3.15 $\overline{\text{ATN2}}$. $\overline{\text{ATN2}}$ is similar to $\overline{\text{ATN}}$, but causes the processor to trap to a different address. $\overline{\text{ATN2}}$ is the preferred line to request service for a polling interrupt operation.

3.16 POLL. The POLL line is used to signal pollable interrupting modules that an identification cycle is coming up. After acknowledging an ATN2 interrupt request, the processor will pull POLL low to indicate that it wants to identify the source of the interrupt. Modules that have interrupts pending should monitor POLL. When POLL, I/O, and REQ are low and WRITE is high, interrupting modules identify themselves by pulling a single bus data line low. The bit to be pulled must be decided by agreement between hardware and firmware, and should be jumperable on hardware boards.

4.0 DC RULES.

Bus signals are generally negative true logic levels. The exceptions are RUN, PWR ON, PRIOR IN, and PRIOR OUT. All bus lines with the exception of PULL and ATN2 have 500-ohm pullup resistors installed on the Backplane PCA. All bus lines except PRIOR IN and PRIOR OUT are connected in parallel to all backplane edge connectors. PRIOR IN is pulled up with 500 ohms at the power supply end of the bus.

4.1 OFF THE BUS. No module may put more than two low-power Schottky input loads on any bus signal; modules needing more must buffer the signals. The only exception to this is PRIOR IN as it will be loaded, at most, by only one module.

4.2 ONTO THE BUS. A bus driver must be capable of driving 28 low-power Schottky loads (14 slots x 2 loads per slot) plus the 500-ohm pullup resistor (which amounts to 22 milliamperes at 0.4 volts). The recommended driver is a 74LS38, although Tri-State may be used.

5.0 TIMING RULES.

5.1 SYS CLK. The 4.915 MHz system clock synchronizes all bus transactions. Bus drivers will change control signals only on the falling edge of the clock. Responding devices are expected to reply immediately upon detecting their addresses, to allow sufficient time for the signals to settle before the next falling clock edge.

- 5.2 PRIORITY IN/PRIORITY OUT. The rules for SYS CLK in section 5.1 above, must also be applied to the priority chain. The priority signal may have to ripple through many modules to reach the last one which might be bidding for the bus at the same time as the first module. The first module must be able to disable the last one by propagating the Priority signal down the entire chain within 200 nanoseconds (plus the setup time of the last module). The results are not predictable if an attempt is made to take control of the bus at other than immediately (less than 50 nanoseconds) after a falling clock edge. Modules which are not controllers must tie PRIOR IN to PRIOR OUT in order to preserve the continuity of the chain.
- 5.3 WAIT. This signal is used to prolong the bus REQ state. The release of WAIT tells the controller that the REQ state can be terminated at the next clock. In order for this to operate properly, data must be stable before the end of REQ (implying that data is driven onto the bus 200 nanoseconds before the end of REQ). In addition, WAIT should only be allowed to go high at a clock edge, and data should be valid and starting to drive the bus at the same time. Thus, data need not be valid and settled, but it must be valid and starting to drive the bus when WAIT is released. This must occur immediately (less than 50 nanoseconds) after a clock edge in order to allow sufficient settling time for the data lines, which have more loading than the WAIT line.
- 5.4 ATN/ATN2. These lines are sampled asynchronously by the processor and have no particular setup requirements. However, for the sake of convention, it has been agreed that an interrupting module will release interrupt request as soon as the processor reads the status of the interrupting module and this must occur within 200 nanoseconds after the end of the status read.
- 5.5 POLL. The POLL line is driven only by the processor and is programmed by the firmware. Typically, three instructions must be executed by the processor in order to perform the poll function. The first instruction causes POLL to be driven low, then an I/O read is performed to obtain

the results of the parallel poll, and finally, an instruction is executed to reset $\overline{\text{POLL}}$ high. Therefore, there will be a minimum of 1.6 microseconds setup and hold time before and after the input instruction which does the parallel poll.

- 5.6 $\overline{\text{PROC ACTIVE}}$. This line also is driven only by the processor and the timing is the same as the timing used to drive $\overline{\text{ADDR}}$, $\overline{\text{WRITE}}$, $\overline{\text{I/O}}$, and bus data lines (all these lines will have 200 nanoseconds setup before $\overline{\text{REQ}}$ and 200 nanoseconds of hold after $\overline{\text{REQ}}$).
- 5.7 $\overline{\text{RUN}}$. $\overline{\text{RUN}}$ is sampled by the processor to determine whether to begin a bus bid state by its controller. If at the time the processor is ready to begin a bus cycle, the $\overline{\text{RUN}}$ line is low, it will cause a holdoff of the cycle until $\overline{\text{RUN}}$ goes high. When $\overline{\text{RUN}}$ goes high, the Bus Bid state will be entered at the next clock edge, and the bus cycle will then complete normally. Once begun, the cycle will complete. $\overline{\text{RUN}}$ prevents the processor from beginning backplane bus cycles, but cannot stop a cycle already in progress. It might be possible to use $\overline{\text{WAIT}}$ to hold a cycle in progress; but if it is a cycle accessing dynamic RAMs, it could cause a refresh failure if the cycle is not allowed to complete at its natural speed.
- 5.8 $\overline{\text{BUSY}}$. $\overline{\text{BUSY}}$ must be pulled low by a controller as soon as the Bus Bid state has been successful. This prevents other controllers from taking control while the bus is in use. $\overline{\text{BUSY}}$ should be released at the end of $\overline{\text{REQ}}$, so that other controllers can use the 200 nanosecond period after $\overline{\text{REQ}}$ to perform their bus bids. In this way, all clock periods can be utilized for data transfer and no time is lost performing purely control functions on the bus.
- 6.0 RULES FOR SLAVE MODULES.
- 6.1 MEMORY MODULES. Refer to figure 4, Typical Memory Module Interface (8K ROM). A memory module will usually contain a sizable contiguous block of memory address space. The module will usually try to have its block

starting address lie on an address which is an integral multiple of the block size. For example, a board with 8K bytes of storage could begin at 0, at 8K, at 16K, at 24K, etc. This results in a board select detector consisting of a 3-bit comparator between $\overline{\text{ADDR15}}$, $\overline{\text{ADDR14}}$, $\overline{\text{ADDR13}}$, and the output of a 3-bit module address switch or jumper on the module. This is ANDed together with I/O high and $\overline{\text{REQ}}$ low to select the module. The direction of transfer is indicated by WRITE, and the less significant address lines ($\overline{\text{ADDR12}}$ through $\overline{\text{ADDR0}}$) select the addressed byte within the module.

- 6.1.1 If the module cannot operate with a 400-nanosecond $\overline{\text{REQ}}$, then it should utilize $\overline{\text{WAIT}}$ to force $\overline{\text{REQ}}$ to last as long as required, consistent with the rules for $\overline{\text{WAIT}}$ outlined in section 5.3. It is not necessary to use $\overline{\text{WAIT}}$ if the module is fast, nor is it necessary that $\overline{\text{WAIT}}$ be pulled the same length of time for reading as for writing. The individual module may take account of its own requirements.
- 6.1.2 If a module contains mixed speeds or types of memory, the various logical blocks should be considered logically separate units, with separate address detectors and separate data drivers. Again, the module may put no more than two active loads on any bus line, and if multiple blocks are loading the same lines, it may be necessary to buffer some lines to comply with these rules.
- 6.2 I/O. Refer to figure 5, Typical I/O Module Interface. I/O modules are addressed differently than memory modules. There are 16 module addresses coded into $\overline{\text{ADDR11}}$, $\overline{\text{ADDR10}}$, $\overline{\text{ADDR9}}$, and $\overline{\text{ADDR4}}$. Eight other address lines ($\overline{\text{ADDR8}}$ through $\overline{\text{ADDR5}}$ and $\overline{\text{ADDR3}}$ through $\overline{\text{ADDR0}}$), are driven by the processor and can be used for any purpose agreed upon consistently between the hardware and firmware. It is expected that these other lines (sometimes called "strokes") act as further address qualifiers or subfunction selectors, although it is not necessary to view them in that manner.

- 6.2.1 In order for a module to recognize its address, it must compare the four module address bits (ADDR11, ADDR10, ADDR9, and ADDR4), and then compare that with I/O low and REQ low. This establishes that the module is currently being addressed, and WRITE again establishes the direction of transfer.
- 6.2.2 There is no current provision for multiple modules to share the same module address (with 16 addresses and only 15 physical backplane slots it is unnecessary to share addresses). If it becomes desirable in the future, it should be considered as a special situation outside of the normal bus rules and handled very carefully.
- 6.2.3 A module which wants to interrupt must pull one or the other (ATN/ATN2) low. As soon as the processor interrogates status from the interrupting module, the module should assume that the processor is about to service the interrupt and it should release ATN/ATN2 at that time. This is independent of the polling identification requirements for pollable interrupting modules. It is not necessary to release ATN/ATN2 as a result of a polling operation. (Refer to section 5.4)
- 6.2.4 A pollable interrupting module which has an interrupt pending (requested but not yet acknowledged) may be polled by the processor. The processor will pull POLL low, and shortly thereafter will perform an input operation at some module address which is unable to respond to an input (read from the display, for example). During this pseudo-input operation, a pollable module which has an interrupt pending, must pull down on one bus data line. The line which is pulled identifies the requesting module to the processor. Since there are eight data lines, up to eight modules may be handled by this method. By agreement, the Cartridge Tape Module pulls on BUS7. (Refer to section 3.16)

7.0 RULES FOR BUS CONTROLLER MODULES.

- 7.0.1 A bus controller requires provision for deriving all the timing and control signals used to transfer data between itself and a slave module, as well as resolving control conflicts between itself and other controller modules. At a minimum, this implies a bus control circuit (figure 6) including control, address, data drivers and/or data receivers. There are other possible bus control circuit designs, but the one shown is the simplest which is suitable for all purposes. All of the features of this circuit may not be needed in all cases. (Refer to section 7.0.4 for the bus controller states, bus controller state diagram (figure 7), and bus controller timing diagram (figure 8) for an explanation of state transitions.)
- 7.0.2 The bus controller circuit shown in figure 6 is suitable for the main processor in the system. This element has two requirements not placed on any other controller--they do the driving of PROC ACTIVE when that module is controlling the bus (driving address lines) and they respond to RUN to hold off transition from Idle to Bus Bid states.
- 7.0.3 Modules other than the processor do not need to use these signals. They must not drive PROC ACTIVE because this would prevent single-step processor cycles from operating predictably. It is not important for non-processor controllers to respond to RUN.
- 7.0.4 RUN and Start Cycle must be present at the same time as a SYS CLK edge, otherwise the cycle start request will be missed. If Start Cycle is a pulse, it may have to be latched (the latch can be cleared by the B flip-flop, which will be set when the bus has been obtained). If the module does not use RUN, and if Start Cycle is a pulse of longer duration than one period of SYS CLK, it is not necessary to latch Start Cycle.

Name	ABC	Signals Driven
=====	===	=====
IDLE	000	-
BUS BID	100	PRIOR OUT
BUS OBTAIN	110	PRIOR OUT, $\overline{\text{BUS0}}$ thru $\overline{\text{BUS7}}$ (if $\overline{\text{WRITE}}$), $\overline{\text{ADDR0}}$ thru $\overline{\text{ADDR15}}$, $\overline{\text{BUSY}}$, $\overline{\text{PROC ACTIVE}}$ (if main processor), $\overline{\text{WRITE}}$ (if write operation), $\overline{\text{I/O}}$ (if not memory operation)
REQUEST	111	Same as 110 above, plus $\overline{\text{REQ}}$
WAIT	011	$\overline{\text{ADDR0}}$ thru $\overline{\text{ADDR15}}$, $\overline{\text{REQ}}$, $\overline{\text{BUSY}}$, $\overline{\text{BUS0}}$ thru $\overline{\text{BUS7}}$ (if $\overline{\text{WRITE}}$), $\overline{\text{WRITE}}$ (if write operation), $\overline{\text{PROC ACTIVE}}$ (if main processor)
RELEASE	001	$\overline{\text{ADDR0}}$ thru $\overline{\text{ADDR15}}$, $\overline{\text{BUS0}}$ thru $\overline{\text{BUS7}}$ (if $\overline{\text{WRITE}}$) $\overline{\text{WRITE}}$ (if write operation), $\overline{\text{I/O}}$ (if not memory operation), $\overline{\text{PROC ACTIVE}}$ (if main processor)
IDLE	000	-

- 7.0.5 The priority chain gate between PRIOR IN and PRIOR OUT functions as a negative OR gate, whose output is low when either input is low. When PRIOR IN is low, the controller is prevented from obtaining the bus (if it is in the Bus Bid state) by the 3-input AND gate between the A and B flip-flops. The signal must also be passed down the priority chain to other lower priority modules which might also be requesting the terminal bus at the same time. (This is true whether this controller is active or not, and hence the gate to pass low PRIOR IN directly to a low PRIOR OUT.)
- 7.0.6 Slave modules are entitled to expect that data and address lines will be valid and stable before, during, and after $\overline{\text{REQ}}$ is low. They use $\overline{\text{REQ}}$ to gate their data onto the bus during a read cycle (implying that data will be changing very shortly after $\overline{\text{REQ}}$ changes). The rise times may be slow since all bus lines are open-collector. To prevent loss of the data, it must be latched up by the controller module. Thresholds may vary, and the rise times of $\overline{\text{REQ}}$ may be slow. Therefore, it is recommended that another, faster version of $\overline{\text{REQ}}$ be generated locally, in parallel with the version used to drive the bus. This fast version of $\overline{\text{REQ}}$ can be a totem pole driver having a fast rise time, and therefore, will occur predictably before $\overline{\text{REQ}}$ on the bus has had a chance to disable the data drivers in the slave module. The drivers provide the required timing for control, address, and data lines. All address, data, I/O, and write signals should be present for longer than the control signals, in order to preserve the desired timing.
